Abstract

We present a formal model of the Pokémon Trading Card Game (TCG) in Lean 4, comprising small-step operational semantics, legality predicates, and global invariants verified across all reachable game states. Our formalization includes 14 action types modeling core gameplay mechanics: playing cards, attaching energy, attacking, retreating, and turn management. We prove key meta-theoretic properties including card conservation, bench limits, prize bounds, and the impossibility of winning on the first turn from a standard starting position. As a payoff, we implement a *certified solver* that selects the damage-maximal legal attack, with machine-checked proofs of both soundness (the returned attack is legal) and optimality (no legal attack deals more damage). The formalization totals approximately 3,500 lines of Lean 4 code with over 80 proven theorems, demonstrating that proof assistants can tractably model the complex rule systems found in commercial trading card games.

1 Introduction

Trading card games (TCGs) present an interesting challenge for formal methods: they combine discrete state spaces with complex, interacting rule systems that evolve through expansions and errata. The Pokémon TCG, with over 25 years of continuous development and thousands of unique cards, exemplifies this complexity. Players must navigate energy attachment rules, type-based weakness and resistance modifiers, status conditions, evolution chains, and per-turn action limits—all while making strategically optimal decisions.

We present PokemonLean, a formalization of core Pokémon TCG mechanics in Lean 4. Our contributions are:

1. A **small-step operational semantics** with 14 action types and decidable legality predicates (Section 2).
2. **Global invariants** ("meta-safety") proven to hold for all reachable game states, including card conservation, zone bounds, and the impossibility of first-turn victories (Section 3).
3. A **certified solver** with machine-checked soundness and optimality theorems for attack selection (Section 4).

1.0.0.1 Scope.

Our model covers the core TCG rules: energy types, attacks with energy costs, weakness ($\times 2$) and resistance (-30), status conditions, evolution, retreat, trainer cards (items, supporters, tools), and prize mechanics. We model a representative fragment sufficient to prove interesting

properties while remaining tractable. Excluded are: stadium cards with global effects, multi-prize EX/V/VMAX knockouts, and complex ability interactions beyond heal/draw effects.

2 Game Model and Semantics

2.0.0.1 State Representation.

A game state comprises two player states and an active player indicator (Figure 1). Each player state tracks: a deck, hand, bench (up to 5 Pokémon), active Pokémon (optional), discard pile, and prize cards. A Pokémon in play carries its base card, accumulated damage, status condition, and attached energy.

2.0.0.2 Actions and Step Function.

We define an `Action` type with 14 constructors covering all major gameplay actions:

```
inductive Action
  | playPokemonToBench (card : Card)
  | playItem (card : Card)
  | playSupporter (card : Card)
  | attachEnergy (energyType : EnergyType)
  | attack (attackIndex : Nat)
  | retreat | endTurn | drawCard | ...
```

The transition function `step : GameState → Action → Except StepError GameState` implements the game rules. For example, playing a Pokémon to the bench requires the card to be in hand and the bench to have fewer than 5 Pokémon:

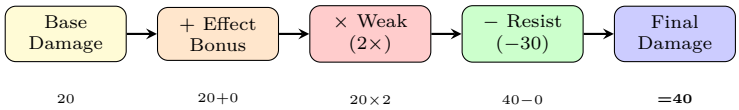

Figure 3 Damage pipeline: Squirtle (Water) attacking Charmander (weak to Water).

```
| .playPokemonToBench card =>
  match removeFirst card playerState.hand with
  | none => .error .cardNotInHand
  | some newHand =>
    if bench.length < benchLimit then
      .ok (addToBench card newHand)
    else .error .benchFull
```

2.0.0.3 Legality Predicates.

For each action, we define a decidable legality predicate `Legal : GameState → Action → Prop`. A key theorem establishes the correspondence between `Legal` and successful stepping:

▶ **Theorem 1** (`step_total_for_legal`). *For any state s and action a, if $Legal(s, a)$ holds, then $step(s, a) = ok(s')$ for some s'.*

The converse also holds: `step_error_iff_not_legal` establishes that stepping errors precisely when the action is illegal.

2.0.0.4 Damage Calculation.

The damage pipeline applies weakness and resistance (Figure 3):

$$damage = \max(0, (base + effects) \times weakness - resistance)$$

where weakness doubles damage if the attacker's type matches the defender's weakness, and resistance subtracts 30. We prove bounds on this calculation:

▶ **Theorem 2** (`damage_nonneg`, `damageBounds`). *Damage is always ≥ 0, and for any attack with base damage b and defender with resistance r: $0 \leq damage \leq 2 \cdot (b + bonus)$.*

3 Meta-Safety Invariants

We define reachability inductively from an initial game state:

```
inductive ReachableFrom (start : GameState) : GameState -> Prop
  | initial : ReachableFrom start start
  | step (h : ReachableFrom start s) (hLegal : Legal s a)
        (hStep : step s a = .ok s') : ReachableFrom start s'
```

We prove several invariants hold for all reachable states:

▶ **Theorem 3** (`reachable_card_conservation`). *The total number of cards across all zones (deck, hand, bench, active, discard, prizes) is invariant: for any reachable state s, $totalCardCount(s) = totalCardCount(initial)$.*

▶ **Theorem 4** (`reachable_bench_bounds`). *For any reachable state, both players' benches have at most 5 Pokémon:* $|s.playerOne.bench| \leq 5 \wedge |s.playerTwo.bench| \leq 5$.

▶ **Theorem 5** (`reachable_prizes_bounds`). *Prize counts remain in* $[0, 6]$*:* $|s.prizes| \leq 6$ *for both players in any reachable state.*

3.0.0.1 No Turn-One Win.

A particularly interesting invariant concerns the impossibility of winning on the first turn from a standard starting position. We define `TurnOneActions` as the set of action sequences available on turn one (no attacking, since the going-first player cannot attack on turn one in standard rules):

▶ **Theorem 6** (`no_turn_one_win`). *For any sequence of actions* $\vec{a}$ *satisfying* `TurnOneActions`*, if* $stepMany(initial, \vec{a}) = ok(s')$*, then* $\neg hasWon(playerOne, s')$.

This theorem captures a fundamental balance property of the game rules.

4 Certified Attack Solver

As a practical payoff, we implement a solver that selects the damage-maximal legal attack. The core function `bestAttack` iterates through available attacks, filtering by energy cost legality and selecting the highest-damage option:

```
def bestAttack (attacker defender : PokemonInPlay)
    : Option (Nat * Attack) :=
  bestAttackFrom attacker defender attacker.card.attacks
```

We prove two key properties:

▶ **Theorem 7** (`bestAttack_sound`). *If* $bestAttack(a, d) = some(i, atk)$*, then* $i < |a.attacks|$ *and the energy cost of* atk *is satisfied by* $a.energy$.

▶ **Theorem 8** (`bestAttack_optimal`). *If* $bestAttack(a, d) = some(i, atk)$*, then for any other legal attack* atk' *at index* j*:* $damage(atk') \leq damage(atk)$.

4.0.0.1 Turn Solver and Two-Ply Lookahead.

We extend the solver to consider energy attachment before attacking (`solveTurn`) and two-turn lookahead (`solveTwoPly`). Both inherit soundness and optimality guarantees:

▶ **Theorem 9** (`solveTwoPly_sound`, `solveTwoPly_optimal`). *The two-ply solver returns a legal attack sequence that maximizes total damage over two turns, among all legal energy attachment and attack choices.*

5 Case Study: Verified Damage Calculation

Consider a concrete scenario (Figure 4): Squirtle (Water-type, 60 HP, attack "Water Gun" with 20 base damage) versus Charmander (Fire-type, 70 HP, weak to Water). Our solver computes:

```
#eval solve squirtleInPlay charmanderInPlay
-- some { attackIndex := 0, expectedDamage := 40,
--        isLethal := false }
```

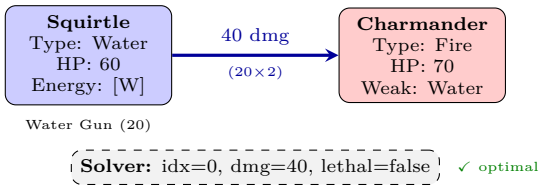

Figure 4 Case study: certified solver selects Water Gun, applying ×2 weakness.

The solver correctly applies the ×2 weakness multiplier ($20 \times 2 = 40$). The soundness theorem guarantees this attack is legal; the optimality theorem guarantees no available attack deals more damage.

6 Related Work and Future Directions

6.0.0.1 Formal Game Verification.

Prior work has formalized simple games like Tetris [1] and game-theoretic properties [3], but to our knowledge, no prior formalization addresses the rule complexity of commercial TCGs. Our work demonstrates that proof assistants can tractably model such systems.

6.0.0.2 Verified Game AI.

Verified game-playing programs exist for simpler domains [2], but typically lack optimality proofs. Our certified solver proves not just correctness but damage-maximality among legal choices.

6.0.0.3 Lean 4 Formalizations.

The Mathlib library [4] provides extensive mathematical foundations. Our work extends Lean 4's application domains to game rule systems, complementing efforts in program verification and mathematics.

6.0.0.4 Future Work.

Several directions remain:

- **Extended coverage**: Stadium cards, abilities with complex triggers, multi-prize mechanics.
- **Probabilistic reasoning**: Coin-flip attacks with expected value calculations (partially implemented).
- **Deck validation**: Proving well-formedness of 60-card decks with the 4-copy rule.
- **Strategy synthesis**: Extending the solver to multi-turn game trees with minimax search.

6.0.0.5 Artifact.

The complete formalization (approximately 3,500 lines of Lean 4) is available as supplementary material. All theorems compile without `sorry` axioms under Lean 4.26.0 with Mathlib. Table 1 summarizes the key proven results.

Table 1 Summary of key theorems proven in the formalization.

Theorem	Category	Property
`step_total_for_legal`	Semantics	Legal actions always succeed
`step_error_iff_not_legal`	Semantics	Errors iff illegal
`reachable_card_conservation`	Invariant	Card count preserved
`reachable_bench_bounds`	Invariant	Bench ≤ 5
`no_turn_one_win`	Invariant	No T1 victory possible
`bestAttack_sound`	Solver	Returns legal attack
`bestAttack_optimal`	Solver	Maximizes damage
`solveTwoPly_optimal`	Solver	2-turn optimality
